

# Time Domain Analysis of Askaryan pulses

P. Miočinović

*University of Hawaii at Manoa, Honolulu, Hawaii, USA*

ARENA Workshop, DESY Zeuthen

May 17, 2005

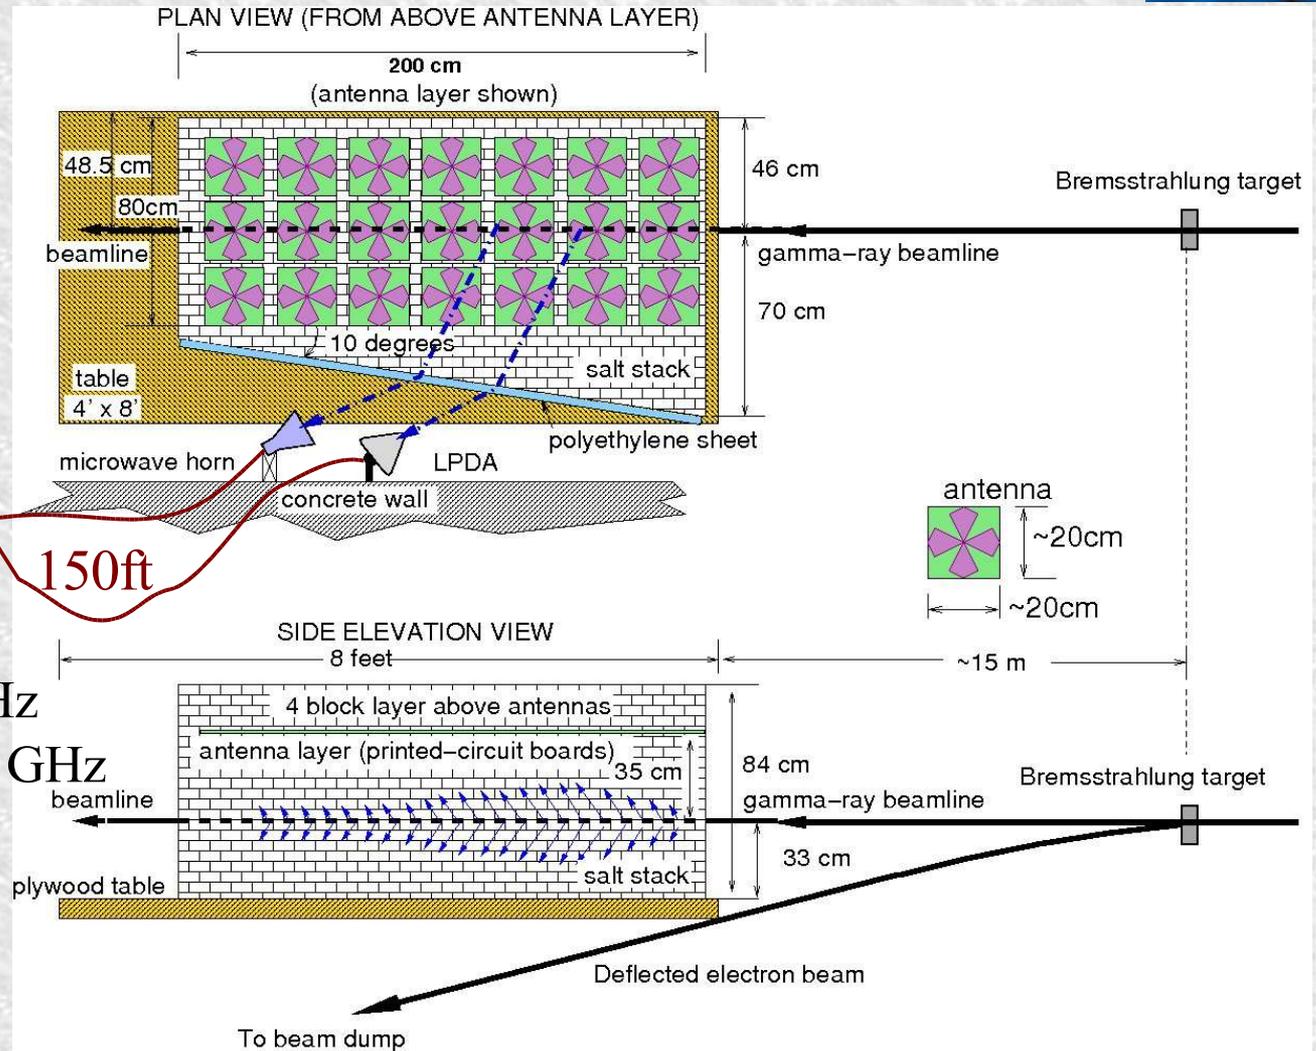

# Outline

- SLAC '02 data collection
- RF calibration and pulse extraction
- Analysis and results
- Summary

# Data taking setup

Digitizing scope

CSA8000

150ft

LPDA

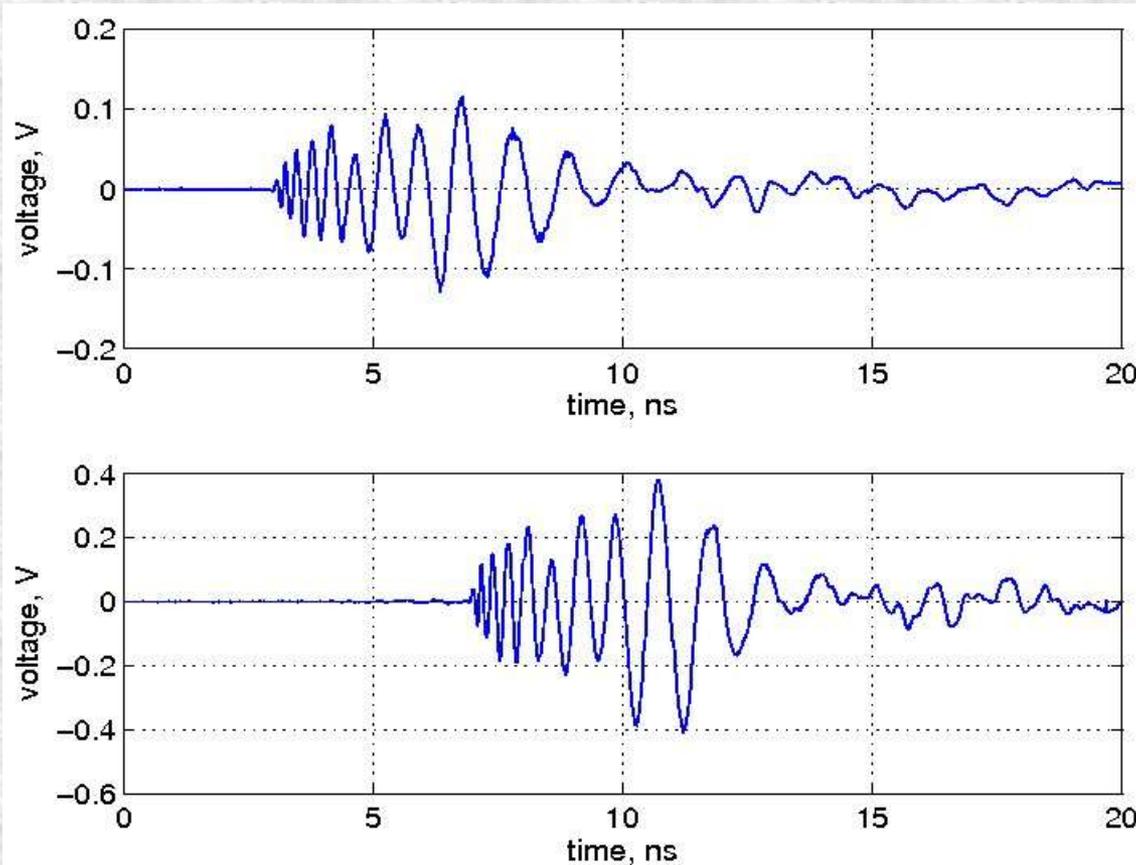

Nominal BW; 1-18 GHz

Measured BW; 0.8-20 GHz

Gain; ~ 4-7 dB

# Raw Askaryan pulse data

Two runs available:

I. Sampled at 50 GS/sec  
no filter  
20 dB attenuator  
 $E_{sh} \sim 1.9 \text{ EeV}$

II. Sampled at 100 GS/sec  
no filter  
no attenuator  
 $E_{sh} \sim 0.66 \text{ EeV}$

# Raw pulse formation

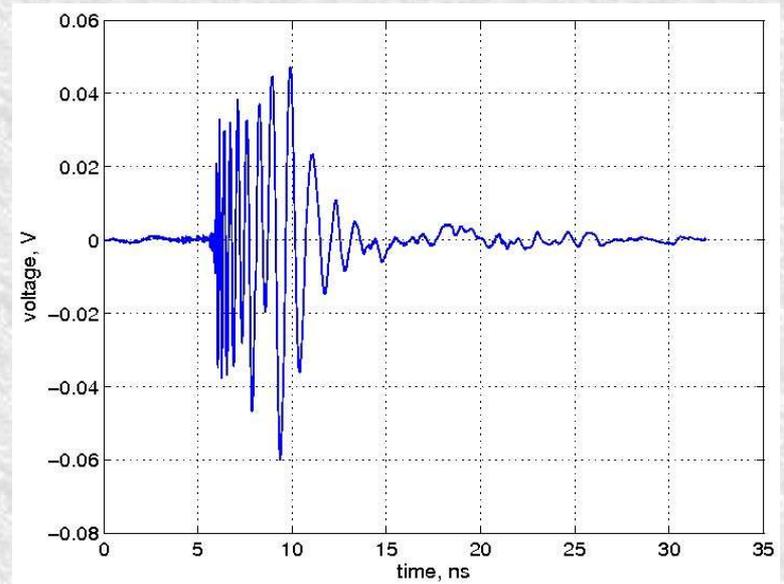

- True pulse is distorted by the antenna and the cable

$$V_{\text{raw}} = E_{\text{Ask}} \circ h_{\text{LPDA}} \circ R_{\text{cable}}$$

- Fourier Domain construction; each element can be treated in terms of a transfer function

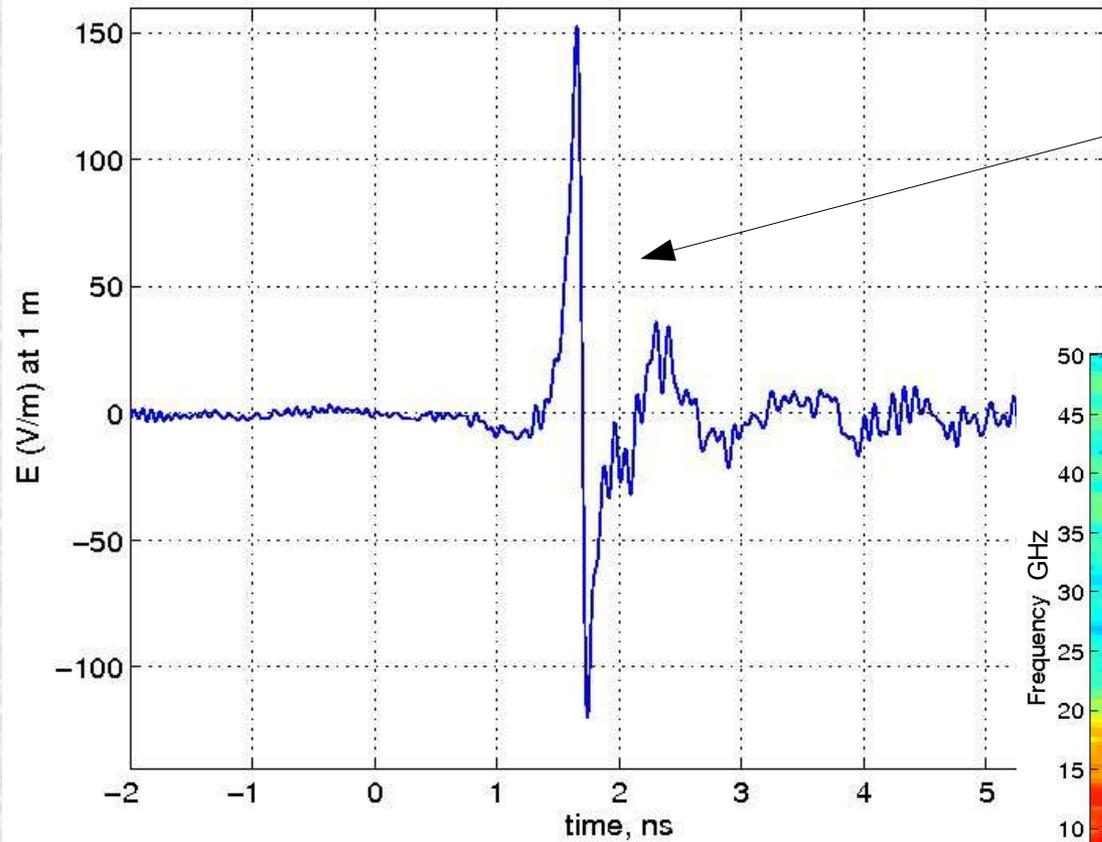

$$H_{\text{raw}} = H_{\text{Ask}} \cdot H_{\text{LPDA}} \cdot H_{\text{cable}}$$

- Extracting the original Askaryan pulse requires the knowledge of antenna and cable complex responses
- Time domain deconvolution can be done through;
  - complex division in Fourier space
  - Weiner algorithm with noise reduction

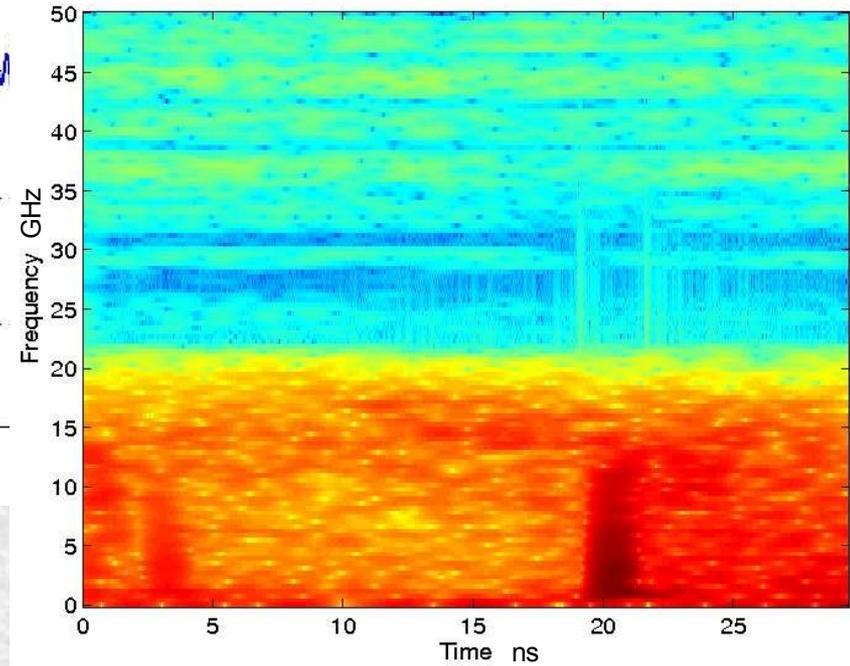

# Measured Askaryan pulse

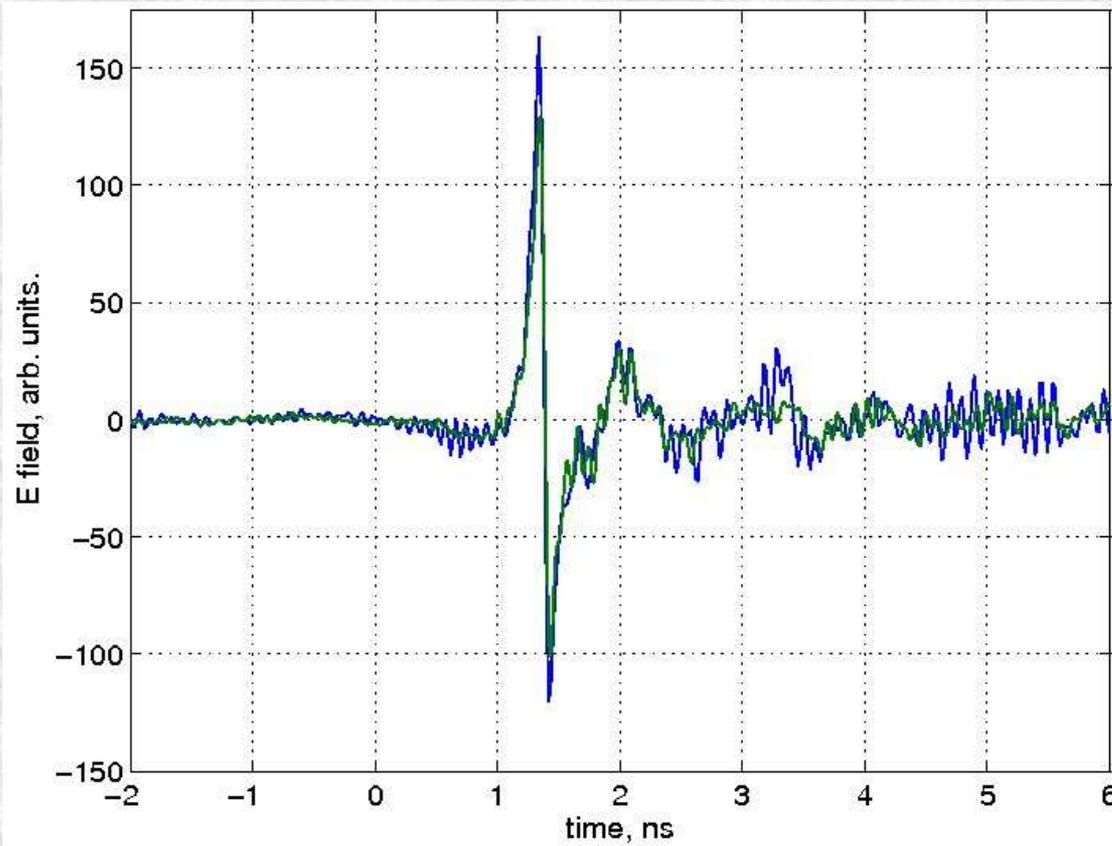

Electric field at antenna

Broadband measure:  
SNR > 1 in 0.5-11.5 GHz  
spectrogram of E-field

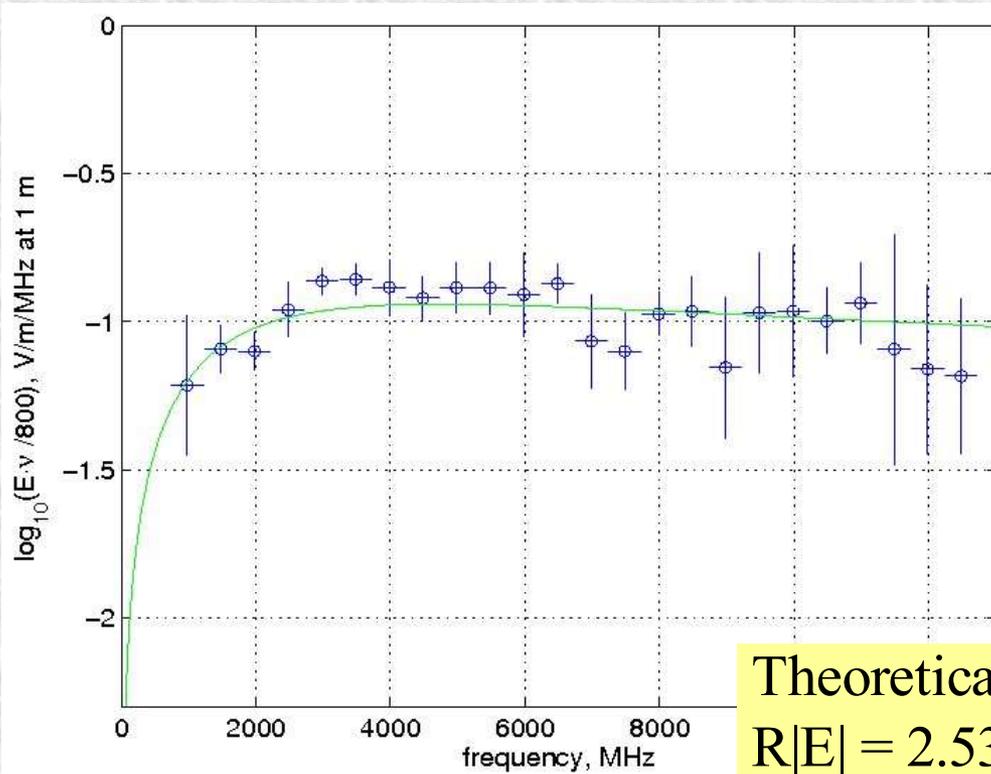

# Comparison of runs

- Pulses rescaled by estimated energy of showers (estimate good to about 20%)
- Askaryan pulse is reproducible, since any shower to shower variations are averaged during a run
- blue trace is noisier due to 20dB attenuator

# Spectral power distribution

Data corrected for dispersion at salt/air interface and for near-field effects:

- Antenna is in the far-field for  $\nu < 800$  MHz; in the **near-field** the shower **coherence region** as seen by the antenna **scales inversely with frequency**
- Thus, the field strength correction  $E \rightarrow E \cdot \nu/800$

Theoretical expectation:

$$R|E| = 2.53 \cdot 10^{-7} \cdot E_{sh} \cdot 0.52 \cdot \nu/\nu_0 \cdot (1 + (\nu/\nu_1)^{1.44})^{-1}$$

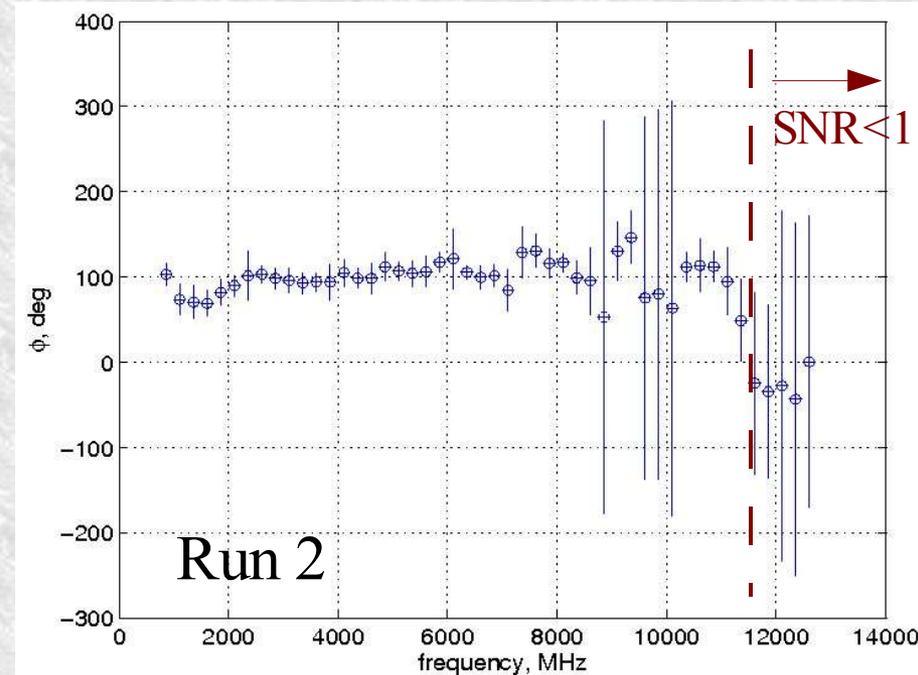

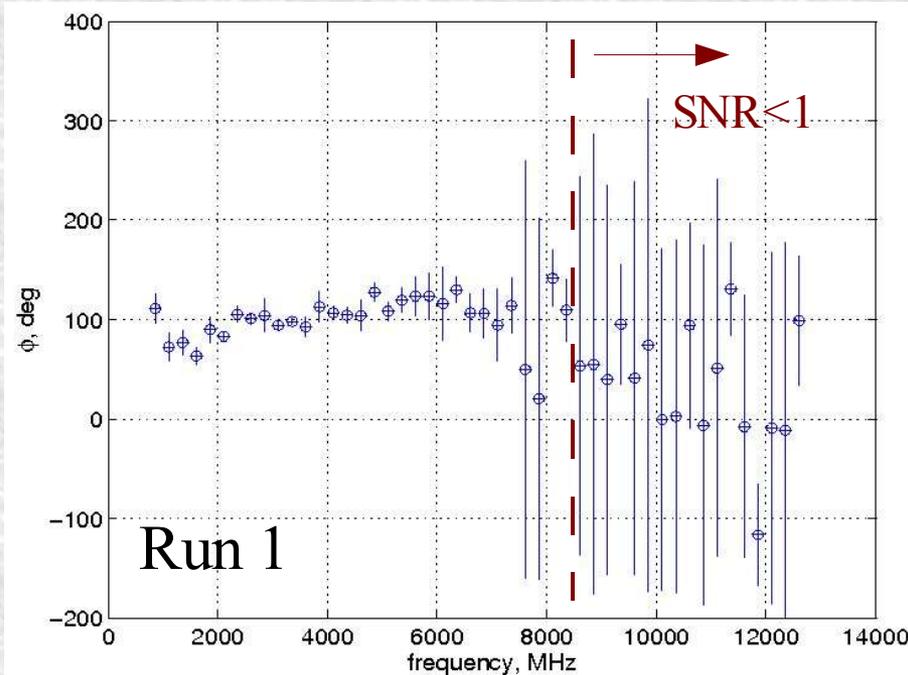

$$E_{sh} = 6.6 \cdot 10^5 \text{ TeV}$$

$$\nu_0 = 1150 \text{ MHz (reference frequency)}$$

$$\nu_1 = 2860 \text{ MHz (decoherence frequency, salt)}$$

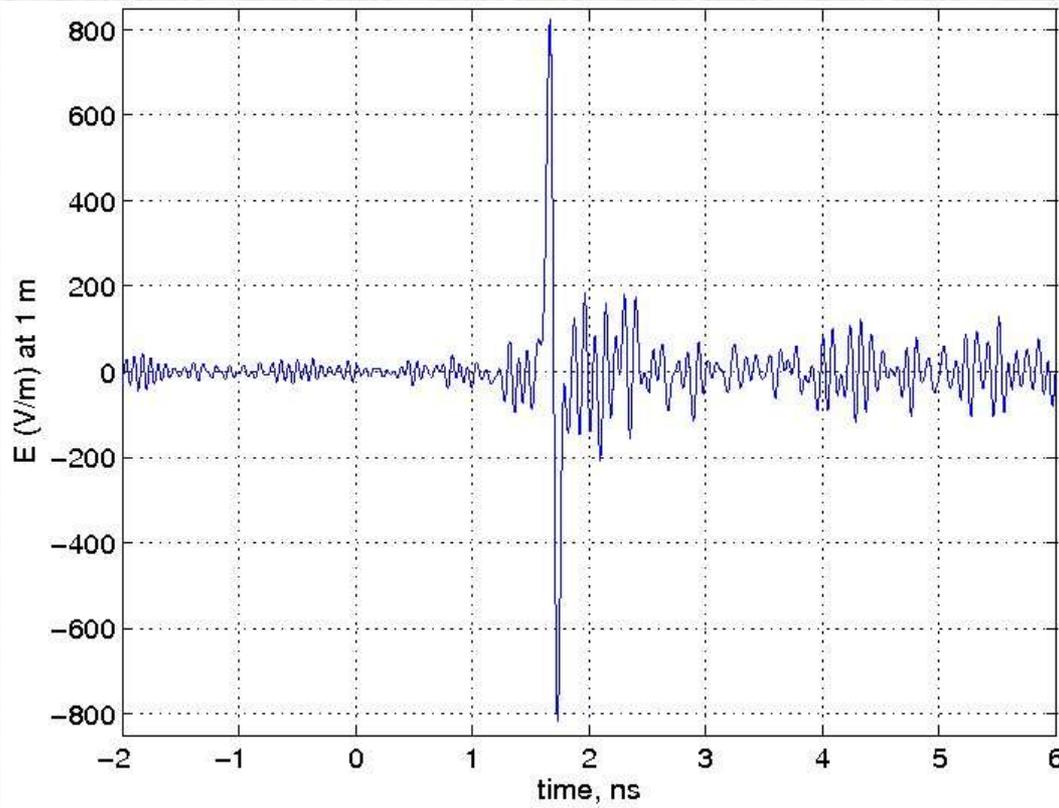

# Phase characteristics

- Phase reference at the pulse mid-point (zero crossing)
- No evidence that phase is running with frequency

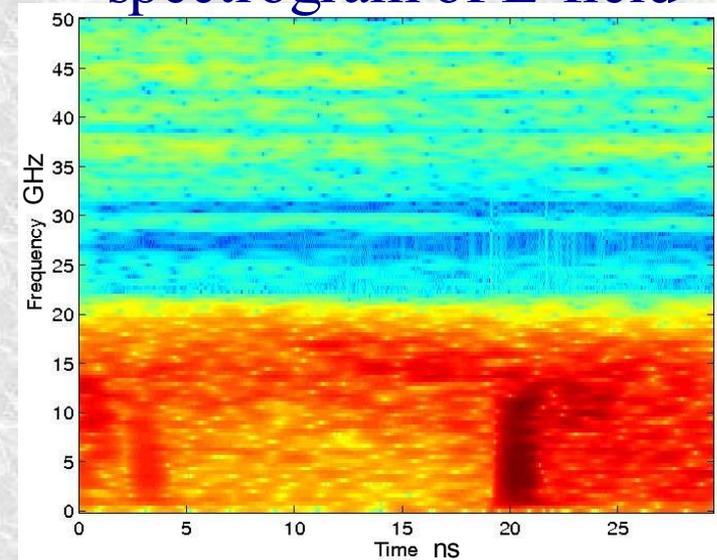

# Askaryan pulse in far-field

E-field at far-field antenna

- Time domain representation of Askaryan pulse with near-field spectral correction
- Pulse appears very symmetric

spectrogram of E-field

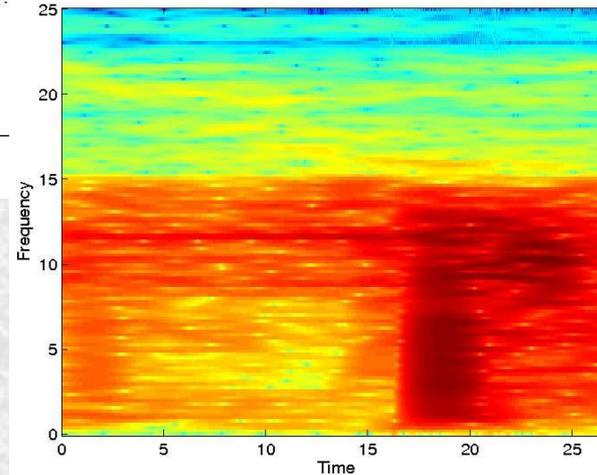

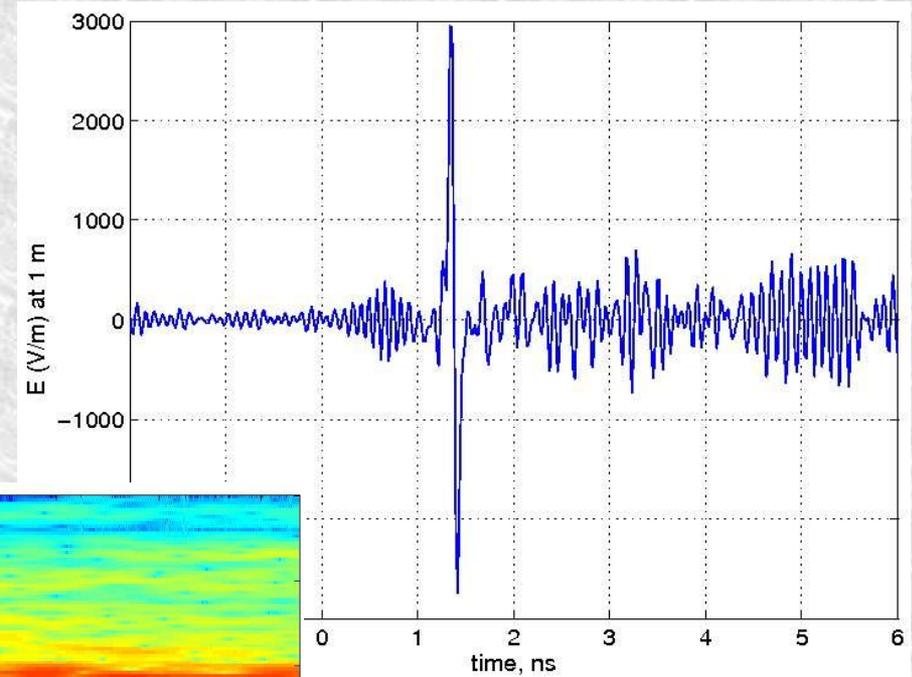

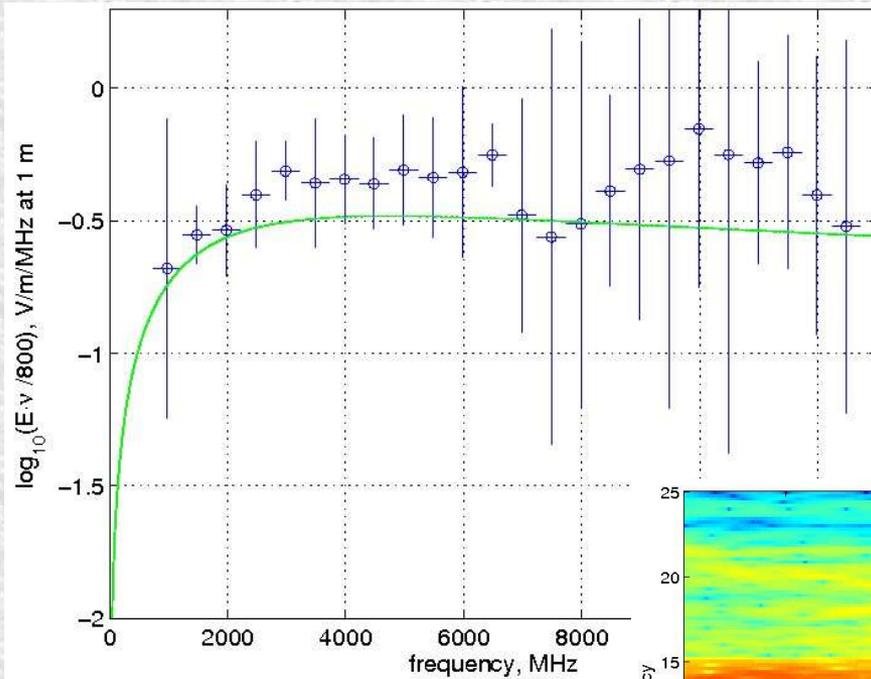

# Summary

- First broadband, time-domain measurement of an Askaryan pulse is reported
- The absolute **RF power** per frequency **agrees well** with theoretical **expectations**
- Pulse **phase characteristics disagree** with (the only!) published **theoretical result**; ZHS '92
  - predictions of pulse phase behavior are very important for maximizing analysis efficiency of RF neutrino experiments
- More accelerator based measurements should be taken to verify time-domain characteristics of Askaryan pulses in different media and over wider energy range

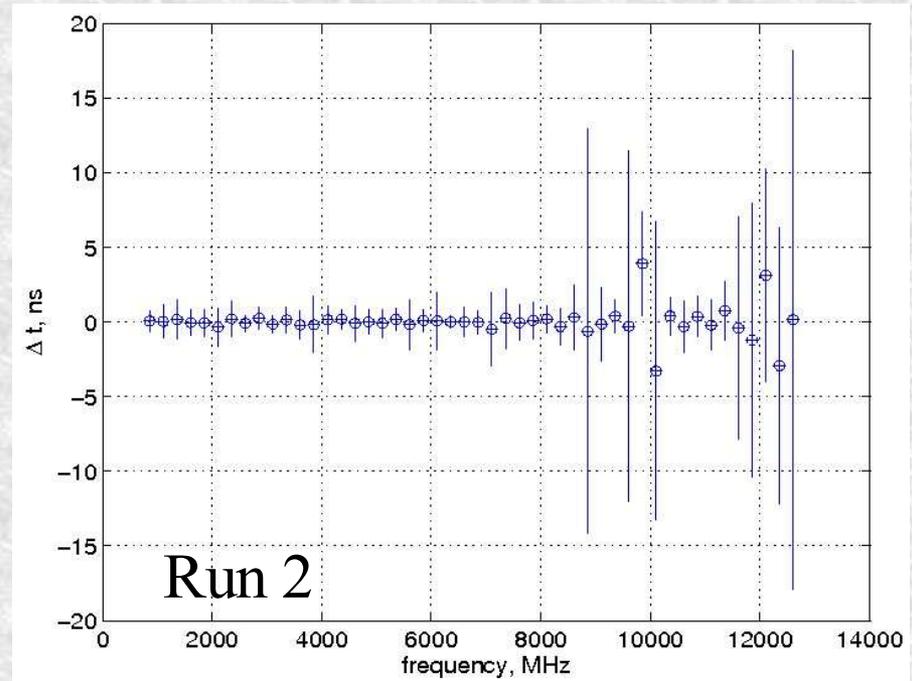

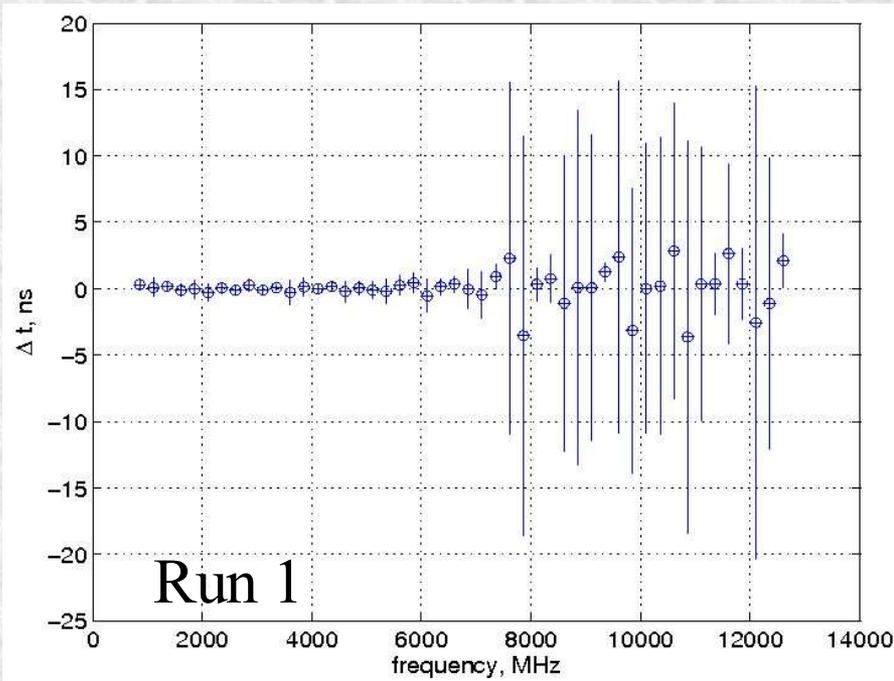

# Run 109 spectrum and “far-field” pulse

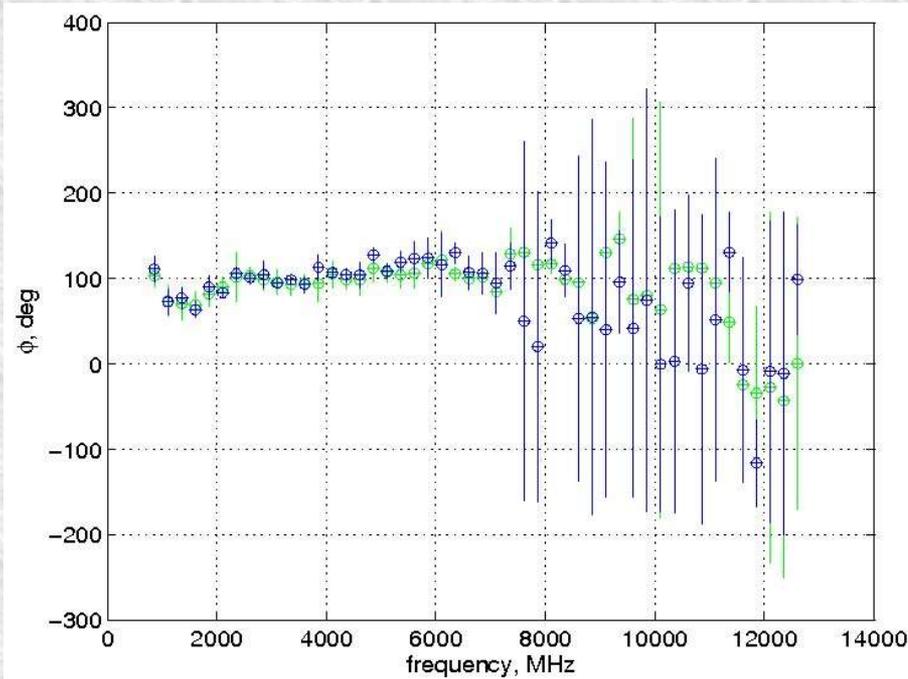

# Group delays

# Phase comparison

## Phase ZHS '92
